

In the class we mainly talked about interesting and concerning cases in the AI industry. AI as a technology has been rising into popularity faster than governments could regulate it. Resulting in it growing into something that some would consider to be hard to control.

At one point, I had a talk about Artificial General Intelligence, a hypothetical advanced form of AI that can match or surpass human capabilities across virtually all cognitive tasks.

We also had a talk of how AI can be susceptible to bias, like how it won't help those of a particular skin color if it's specifically designed to do so. Or how it does its testing on solely male test subjects and examples, so the final product and its flaws may hit women harder than men. Those biases are the result of the designer.

We also discussed on the topic of AI displacing jobs. Where from what I got is with the rise of AI, much like with the rise of computers, there will be displacements in certain sectors as well as the creation of new jobs for others. Though such displacement could also be the result of businesses and executives who prioritize saving money above all else.

We also touched on potential security issues regarding AI, including the infamous trick where a hacker can tell an AI to forget all previous prompts it had to give it new, potentially more malicious, instructions.

I'm just writing on and on with the class, but that's what I can remember I got from it.
