

At the start of class, we discussed AI inaccuracies regarding security and age restrictions. The likelihood is that, with the rise of AI, the U.S. government is watching your every move. I also remember, near the start of class, the phrase 'Money never sleeps'. Which is fitting considering that the topic we were getting into was AI in Finance.

I learned Machine Learning (which serves as the brain), Natural Language Processing (which serves as the speech), and Computer Vision (which serves as the eyes). NLP check scanning is one aspect of AI, particularly NLP applied to finance. The advantages of AI in finance, as presented, include faster and more reliable processes, better risk analysis and mitigation, personalized services, and lower operational costs.

We then talked about AI in Algorithmic Trading, noting that its advantages are numerous. From high-frequency trading executing thousands of trades in seconds, to pattern recognition, to detecting market opportunities, to forecasting market trends through predictive analytics.

AI is also applied to Fraud Detection to enable real-time monitoring, anomaly detection, and behavioral analysis. AI is also applied in Credit Scoring, Customer Service, Risk Management, Insurance, Financial Forecasting, Blockchain Applications, and more.

We also went through ethical considerations. Such as gender bias in hiring men over women at Microsoft offices, appropriate compensation for data breaches, the requirement to have a human in the loop for all decisions in the world of finance, etc.
