

We talked about AI in entertainment. And since entertainment spans a wide range of fields, there are many applications of AI across those fields.

We discussed music first, where we experimented with an AI that generates music from prompts, like the one that generated a romantic song for one of our classmates. It composes music using Neural Networks, analyzes patterns in music, and uses deep learning models to learn musical structures.

Then we discussed AI in art and Design. The key technologies here are Generative Adversarial Networks (GANs), neural networks, a generator, and a discriminator, in a deep learning architecture that compete to create highly realistic data: the generator generates images, and the discriminator evaluates them. Two popular tools for art generation are DeepArt and Artbreeder.

Then we finally discussed AI in Writing. The key technology in this one is Natural Language Generation (NLG), which enables AI to write text that mimics human language. Two advanced models for writing are GPT-3 and GPT-4.

Like most AI applications, there are some ethical and security issues to consider such as users being exposed only to similar content, extensive data collection on user behavior, need for clarity on how recommendations are made, and deepfakes, where a person's likeness is replaced with someone else's, and, in scenario, using AI to generate an artificial image or video of a real person's likeness for malicious purposes. There are other concerns, such as authenticity and ownership, consent and privacy, accountability for misuse of AI content, and the societal impact that comes with it. Such as job displacement, content homogenization, and rising skepticism towards digital content.

As such, we need to maintain responsibility in AI development and uphold transparency, inclusivity, and accountability to avoid future issues, concerns, problems, and potential disasters. Such as clear communication about AI use, the use of diverse datasets to avoid bias, and mechanisms to hold creators accountable.
